

MONSID®

# Technical Briefing

July 2023

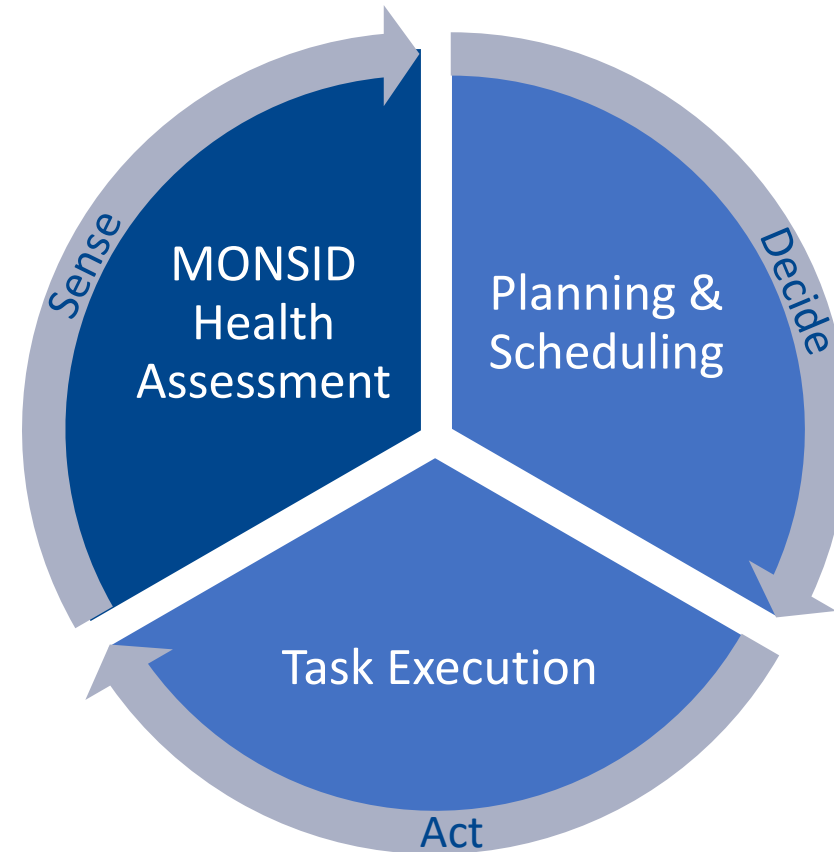

# Health Assessment - The Big Picture

System Health Assessment is critical to system operations

- A key part of Sense Decide Act for mission operations
- Enables onboard resource management: replan in the face of opportunities or threats
- Enables targeted responses and autonomous recovery: operate through failures
- Enables improved decision making for human operators

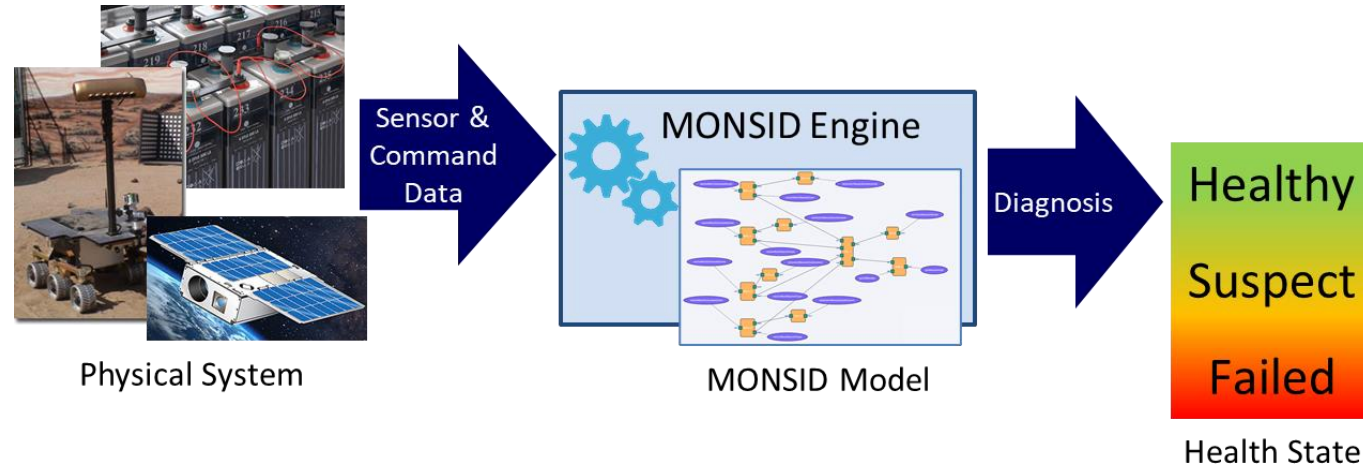

MONSID provides continuous health assessment on board or remotely

# What is MONSID?

Model-Based Off Nominal State Identification and Detection

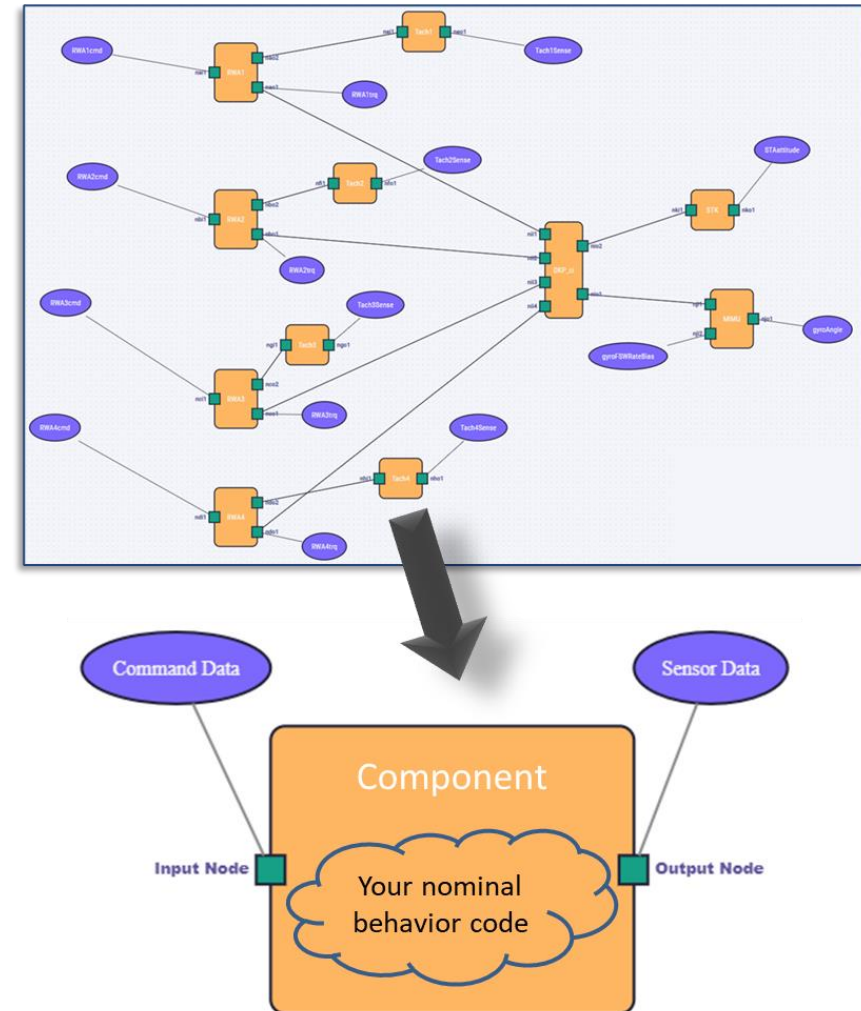

**MONSID** consists of:

- Diagnostic Engine (application independent)
- Model capturing nominal system behavior (application specific, network of hardware components)
- Sensor and Command data are inputs to MONSID Model
  - Inputs are propagated through model
  - Utilizes Constraint Suspension technique to detect and isolate faults
- MONSID outputs health state of system components
- Utilizes only nominal behavior – fault models not needed to isolate faults

# MONSID Models System Behavior

- Components
  - Represent your system's hardware/functions
  - Describe nominal/expected behavior
  - Can be equations, lookups, curve fits, etc.
  - Have input (left) and output (right) nodes – roughly equivalent to functional flow
- Connections
  - Link components together
  - Allow data to propagate through model
- Sensor & Command data
  - Provide inputs to the model from physical system
  - Are compared to modeled values at the nodes

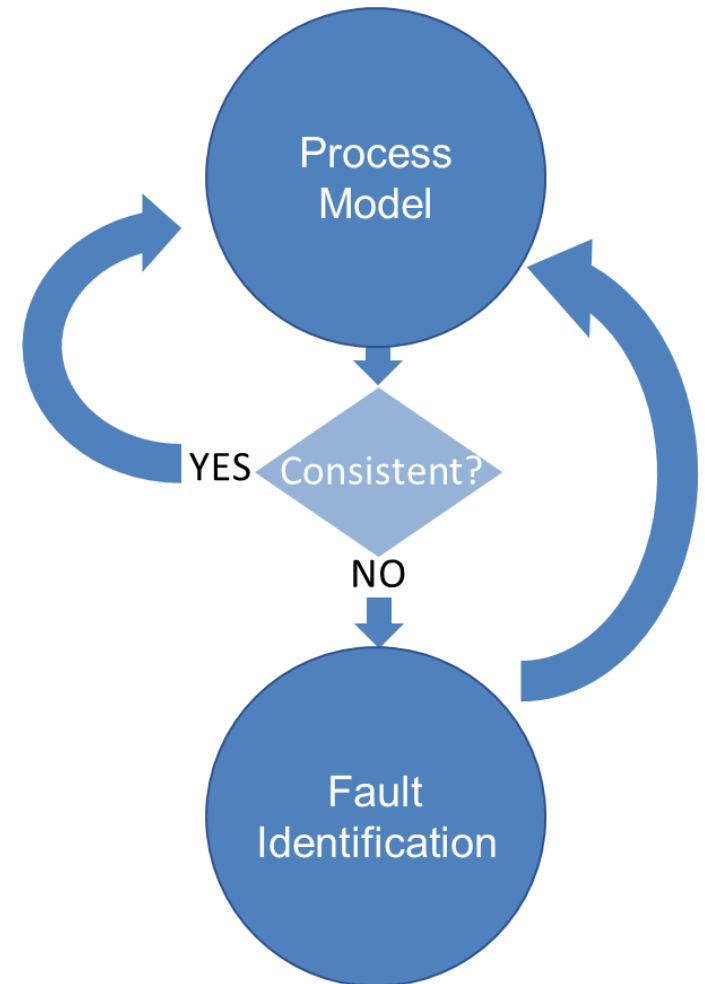

# MONSID Engine Evaluates System Behavior

## Engine Overview

- Command and sensor data are fed to MONSID Engine at each time slice
  - Model processes one or more samples to *establish its initial state*
- Engine processes the model at each data slice
  - Propagates sensor data through model
  - Compares behavior between physical system and model
    - Consistent behavior -> Healthy
    - Inconsistent behavior -> Faulty
- When a fault is detected:
  - Engine analyzes discrepancies to identify faulty component or sensor
  - Identification based on a constraint suspension technique (deterministic, iterative algorithm)

# MONSID API and Tool Suite

```
...
void Application::Initialize() {
    // ...
}
...
// ...
}
...

```

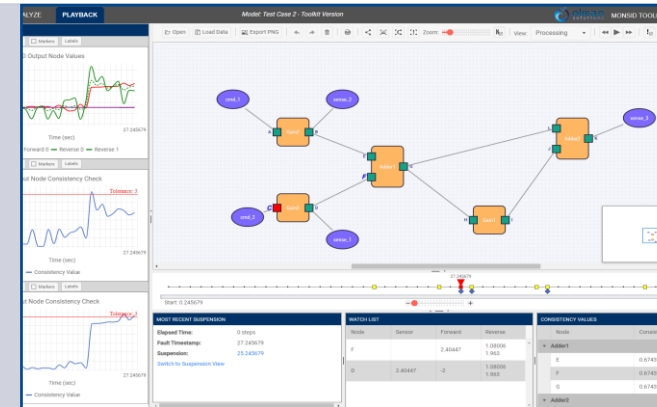

```

Usage: monsid-cli actions [options]

:: Actions:
::
:: -bc          Build Check. Checks for errors in the Build method of the
::              specified model so that it can run in the MONSID engine.
::              Prerequisite parameters: -l, -m
::              Create a Consistency Value file from the specified playback
::              file. The file lists each node's consistency value and
::              tolerance delta for each timeslice.
::              Prerequisite parameters: -p
::
:: General options:
::
:: -l <library>  Library or assembly containing the MONSID model
:: -m <modelname> Model name or type name. Used to locate the method
::               named <createcodebase>.
:: -p <file>     Playback file name. This file is created by monsid-exec.
::
:: Display options:
::
:: -v           Turn on verbose output

```

- ## API
- Compact and modular API
  - Platform independent
    - C#, C++, C versions available
    - Works with ROS, cFS, F-Prime
  - API enables your own tool creation and customizations
  - Developer's Guide and code examples

- ## Command Line Tools
- MONSID executive
    - CSV processor for MONSID Engine
    - Creates playback files for Toolkit
  - MONSID cli
    - Model build checker
    - Post-analysis utilities

- ## Toolkit web app
- Visual model design
  - Diagnosis visualization
  - Fault window parameter tuning
  - Livestream MONSID Engine results
  - Analyze fault diagnosis performance using model topology
  - Validate model topology

# Benefits of MONSID

## Model-based Fault Management

- MONSID engine is reusable, only models change with application
- Potential to **diagnose unforeseen faults** - fault models not required
- Unlike limit checking, MONSID provides continuous estimate of health state
- Relatively simple models proven effective

## Flexible Software Development

- **Small footprint, lightweight**, minimal RAM requirements for use on single board computers, SOC, MOC, laptops
- Designed for real-time monitoring
- Can be used in conjunction with existing fault response/recovery mechanisms

## Supports Integration and Test

- Effective even for sensor-poor systems
- FM design can be started earlier in FM lifecycle
- Uncovers control software and operation errors
- Models validated once, can be used in **all phases** of project cycle

## Supports Autonomy

- Can be integrated with Planner/Scheduler
- Enables targeted responses to anomalies
- **Complementary** to other FM technologies
- Can also be used in a ground system for **Operator support and training**

# Application Highlights

## AFRL Autonomy Test Bed

- Integrated with cFS (publish/subscribe middleware)
- Detected both injected and real hardware faults

## CubeSats

- Lunar Flashlight I&T tool
- ASTERIA – integrated with FSW, tested with ACS flight data

## NASA JPL Athena test rover

- Found off nominal behaviors - Terrain-induced stalls
- Identified hardware faults – motor stalls, over temp

## Caltech state of the art test facility

- MONSID implemented on reaction wheel and thruster 6-DOF platforms using ROS
- Identified injected reaction wheel failures

## Technology Development and Studies

- Part of NASA JPL's Autonomy Framework
- Target system for Model-Based System Assurance techniques
